## 1 Important Rules:

- It is really important that Bob picks a new ephemeral key  $b$  for every message.  
If Bob uses the same  $b$  value to encrypt another message  $m_2$ :

Ciphertext:

$$r_1 = \alpha^a \pmod{p}$$

$$t_1 = m \cdot B^b \pmod{p}$$

Then, the  $r$  value stays the same

$$r_2 = \alpha^a \pmod{p}$$

$$t_2 = m \cdot B^b \pmod{p}$$

So  $r_1 = r_2$ .

- If Eve does a known plaintext attack on  $m_2$ , she can find  $B^b = t_2 \cdot (m_2)^{-1} \pmod{p}$

- She never has to solve the Discrete Log Problem.

- Notice that if Eve can make an educated guess as to what the plaintext is, She can't check to see if she was right because every ephemeral key produces a different value of  $t$ .

## 2 Contrast This With RSA:

- If Eve ever guesses  $m$ , she can check to see if she was right by computing  $m^e \pmod{n}$  to see if she computes the ciphertext.
- To defend against this with RSA, it is important to pad your messages.
  - Pad: append a random number to the end of the message.
  - This should be used whenever possible in applied cryptography .

## 3 Attacking the Discrete Log Problem:

### Brute Force:

$p$  is the modulus, where  $p$  is roughly  $2^b$   
-  $b$  is the number of bits in  $p$

Goal: Solve  $y = a^x \pmod{p}$  for  $x$ . (We know  $y$ ,  $a$ , and  $b$ )

Try all possibilities for  $x$  where  $1 < x < p - 1$

- This has a running time of  $O(p) = O(2^b)$ . This is exponential time...

### Baby-step Giant-step:

Goal: Solve  $y = a^x \pmod{p}$  for  $x$ . (We know  $y$ ,  $a$ , and  $b$ )

Let  $N = \text{Ceiling}(\sqrt{p})$

Think about  $x$  as a number written in base  $N$

- Note that  $N^2 = \text{Ceiling}(\sqrt{p})^2 > p > x$

So  $x = i \cdot N + j$

-  $i$  and  $j$  are digits in base  $N$  and between  $0$  and  $N$

Goal: Solve for i and j:

$$y = a^{i \cdot N + j} \pmod{p}$$
$$y = a^{i \cdot N} \cdot a^j \pmod{p}$$

$$y \cdot a^{-iN} = a^j$$

- This is the same trick as meet in the middle.

Create tables then find the entry that shows up in both tables. There will only be 1 value in both tables.

Table1:

Baby steps:

All possibilities for  $a^j \pmod{p}$   $0 \leq j \leq N$

Table 2:

Giant steps:

$$y \cdot a^{-iN} \pmod{p} = y \cdot (a^{-1})^n \pmod{p}$$

Running time is  $O(3N) = O(N) = O(\sqrt{p}) = O(2^{b/2})$

**Example:**

Find x where  $7^x = 11 \pmod{23}$  using baby-step giant-step

$$N = \sqrt{23} = 5$$

Baby steps:

$$7^i \pmod{23}.$$

$$0 \leq i < 5$$

$$7^0 = 1 \pmod{23}$$

$$7^1 = 7 \pmod{23}$$

$$7^2 = 49 = 3 \pmod{23}$$

$$7^3 = 21 \pmod{23}$$

$$7^4 = -2 \cdot 7 = -14 = 9 \pmod{23}$$

table:

$$0 \text{ --- } 1$$

$$1 \text{ --- } 7$$

$$2 \text{ --- } 3$$

$$3 \text{ --- } 21$$

$$4 \text{ --- } 9$$

Giant steps:

$$11 \cdot 7^{-j \cdot 5} = 11 \cdot (7^{-5})^j \pmod{p}$$

$$0 \leq j < N$$

$7^{-5} = 10 \pmod{23}$  by the extended Euclidean algorithm.

Table:

$$10^2 = 100 = 8 \pmod{23}$$

$$10^4 = 64 = 18 \pmod{23}$$

$$10^5 = 18 \cdot 10 = -50 = -4 = 19 \pmod{23}$$

table:

$$0 \text{ --- } 11 \pmod{23}$$

$$1 \text{ --- } 21 \pmod{23}$$

$$2 \text{ --- } 15 \pmod{23}$$

21 is in both tables, so  $j$  is 1 and  $i$  is 3.  $x = 3N + 1 = 15 + 1 = 16$ .
