## Factoring Trick:

If  $a^2 \equiv b^2 \pmod{n}$  but  $a \not\equiv b \pmod{n}$  then  $n$  is composite and  $\gcd(n, a-b) = d$  is a nontrivial factor of  $n$

## Factoring:

Brute Force

—Worse Case:  $n = p * q$  and  $p, q \approx \sqrt{n}$

—Try dividing  $n$  by integers from 2 to  $\sqrt{n}$  until we find a divisor:  $O(\sqrt{n})$

—“Size” of  $n$  is the number of bits  $N = \lceil \log_2(n) \rceil$  so  $O(2^{N/2})$

So we want to use the factoring trick

—Naive Approach: Pick random values of  $a$ ,  $\sqrt{n} \leq a \leq n$

—Compute:  $c = a^2 \% n$

—Check to see if  $b = \sqrt{c}$  is an integer

—If it is we use the factoring trick

— $b^2 \equiv a^2 \pmod{n}$  so  $\gcd(n, a-b)$  is a factor

—How long do we expect this to take?

—Each time we compute  $c$  we get a random number between 0 and  $n-1$

— $n$  choices for  $c$ ,  $\sqrt{n}$  choices of them are perfect squares

—Probability of success is  $\sqrt{n}/n = 1/\sqrt{n}$

—On average this takes  $\sqrt{n}$  tries:  $O(\sqrt{n})$

—Dixon's Factorization Algorithm

—Pick a bound  $B$ , we only want to consider primes smaller than  $B$

—Pick random values of  $a$ , compute  $c = a^2 \% n$

—If all prime factors of  $c$  are smaller than  $B$  we add it to our list (Divide  $c$  by all small primes up to  $B$ )

—Keep a list of  $a$ 's and corresponding  $c$ 's

—Need to get a list that has one more entry than there are primes up to  $B$

—Now we find a subset of  $c$ 's that make a square

—Let  $X$  be the product of all the  $a$ 's we used while making the square and  $Y$

—be the product of all the  $c$ 's used to make the square and  $W^2 = Y$

—Now  $W^2 \equiv X^2 \pmod{n}$  so we can use the factoring trick to factor  $n$
