

Class Notes 2/16/17

David Rogers

March 8, 2017

Starting from where last class left off;

$$\frac{P(\text{message} = 'YES') * P(\text{key} = K2)}{P(\text{key} = K1) * P(\text{message} = 'NO') + P(\text{key} = K2) * P(\text{message} = 'YES')}$$

What we get from the tables mentioned last class is:

$$\frac{(1/4) * (1/3)}{(1/3) * (3/4) + (1/4) * (1/3)} = 1/4 \text{ so Eve didnt learn anything.}$$

What if eve captures 7 instead?

Eve knows something then. A cryptosystem has perfect secrecy if for any ciphertext 'C' and any message 'M' $P(\text{message in 'M' | Ciphertext 'C'}) = P(\text{message is 'M'})$

DOWNSIDES: Alice and Bob have to share the key, they can only use it once .

Theorem: The one-time-pod has perfect secrecy

The next part is just showing different short cuts how to find the GCD of numbers much faster.

1. Compute $GCD(6,9)=3$
2. factor m,n take prime powers that divide both

$$\begin{aligned} GCD(12,30) &= 6 \\ 12 &= 2 * 2 * 3 \\ 30 &= 2 * 3 * 5 \end{aligned}$$

so group the $2 * 3$ which both have in common and you have 6

3. This is the fast method: Euclids algorithm

$$\begin{aligned} GCD(M,N) &= d \\ d &\text{ divides } (m-n) \\ d &\text{ divides } (m-a*n) \end{aligned}$$

Use division with remainder
 $n/m=a$ with remainder r
 d still divides r
 $\text{GCD}(m,n) = \text{GCD}(n,r)$

Ex. $\text{GCD}(1317,56)$
is simplified to $\text{GCD}(56,29)$ which is obtained by dividing $56/1317$
This gives you remainder 29

Then divide $29/56$ which gives you remainder 27

So the $\text{GCD}(29,27)$

) You keep repeating this process until the divisor is 1 or cannot be simplified any further.
