#### GROUP ACTIONS ON SURFACES

For the purposes of this talk, a discrete group acting on a surface is a set of one to one functions from the points on a compact surface in three dimensions onto itself. The composition of two functions in the set is another function in the set and the inverse of any function in the set is also in the set.

These two actions would generate a group of 8 symmetries of the donut which have the same structure as the symmetries of a square.

These two actions would generate a group of 8 symmetries of the donut which have the same structure as the symmetries of a square.

This is an action of the dihedral group,  $D_8$  on a torus (donut).

These two actions would generate a group of 8 symmetries of the donut which have the same structure as the symmetries of a square.

This is an action of the dihedral group,  $D_8$  on a torus (donut).

Since a donut has 1 hole, this would be called a genus 1 action of  $D_8$ .

This region is called a fundamental region for this action of  $D_8$ .

This region is called a fundamental region for this action of  $D_8$ .

The reflections reverse the orientation of the surface and the rotations preserve the orientation.

This region is called a fundamental region for this action of  $D_8$ .

The reflections reverse the orientation of the surface and the rotations preserve the orientation.

Unfortunately, there are a lot of finite groups which cannot act on a sphere or torus. Therefore, we have to figure out how to construct more complicated surfaces.

The group elements will be represented by transformations of a plane. Then by identifying certain regions of the plane we will obtain a compact surface.

Let *G* be a finite group.

Let *G* be a finite group.

Burnside used inversion in a circle as the transformation of the plane. Inversion reverses the orientation of a plane and so each element of a finite group is represented by a composition of two inversions. This gives an orientation preserving action on the plane.

Let *G* be a finite group.

Burnside used inversion in a circle as the transformation of the plane. Inversion reverses the orientation of a plane and so each element of a finite group is represented by a composition of two inversions. This gives an orientation preserving action on the plane.

There is a connected region of the surface, called the Fundamental Region, that is moved around the surface by the inversions.

Regions can be divided into ones where the orientation is preserved (white) and regions where the orientation if reversed (black). A fundamental region of the group is a union of one white and one black region.

Regions can be divided into ones where the orientation is preserved (white) and regions where the orientation if reversed (black). A fundamental region of the group is a union of one white and one black region.

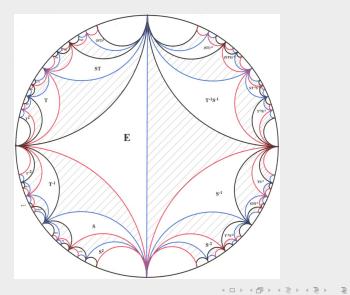

In the next slide, we will look at an infinite group with 2 generators acting on the Poincare disk model of Hyperbolic space.

Regions can be divided into ones where the orientation is preserved (white) and regions where the orientation if reversed (black). A fundamental region of the group is a union of one white and one black region.

In the next slide, we will look at an infinite group with 2 generators acting on the Poincare disk model of Hyperbolic space.

The elements S, T, and U are reflections in a circle and these generators satisfy STU = 1. So  $U = T^{-1}S^{-1}$  and S and T generate a free group.

# Background

GROUP ACTIONS ON SURFACES

900

The group given by  $\langle S, T | S^m = T^n = (ST)^q \rangle$  is called a Triangle Group and designated T(m, n, q).

< ロ > < 同 > < 三 > < 三

The group given by  $\langle S, T | S^m = T^n = (ST)^q \rangle$  is called a Triangle Group and designated T(m, n, q).

Any finite 2 generator group is the image of a triangle group.

< ロト < 同ト < 三ト < 三ト

The group given by  $\langle S, T | S^m = T^n = (ST)^q \rangle$  is called a Triangle Group and designated T(m, n, q).

Any finite 2 generator group is the image of a triangle group.

In the diagram on the Poincare disk, the regions containing words which realize the same group element are identified. This effectively "folds the hyperbolic plane into a compact surface."

The Quaternion Group *Q* is a non-abelian group with 8 elements and it has presentation  $Q = \langle R, S | R^4 = S^4 = 1, R^2 = S^2, R^{-1}SR = S^{-1} \rangle.$ 

The Quaternion Group *Q* is a non-abelian group with 8 elements and it has presentation  $Q = \langle R, S | R^4 = S^4 = 1, R^2 = S^2, R^{-1}SR = S^{-1} \rangle.$ 

It is easy to see that Q is an image of T(4, 4, 4).

The Quaternion Group *Q* is a non-abelian group with 8 elements and it has presentation  $Q = \langle R, S | R^4 = S^4 = 1, R^2 = S^2, R^{-1}SR = S^{-1} \rangle.$ 

It is easy to see that Q is an image of T(4, 4, 4).

It also has 16 faces (8 white and 8 black). By drawing just these 16 faces and identifying edges, we can show that the surface has 6 vertices and each vertex has order 8 (corresponding to a rotation of order 4).

The Quaternion Group *Q* is a non-abelian group with 8 elements and it has presentation  $Q = \langle R, S | R^4 = S^4 = 1, R^2 = S^2, R^{-1}SR = S^{-1} \rangle.$ 

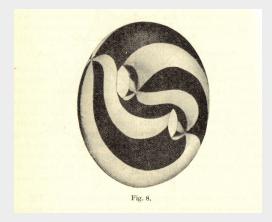

It is easy to see that Q is an image of T(4, 4, 4).

It also has 16 faces (8 white and 8 black). By drawing just these 16 faces and identifying edges, we can show that the surface has 6 vertices and each vertex has order 8 (corresponding to a rotation of order 4).

Therefore it has 24 edges.

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group  $\Gamma$  by a surface group K.

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group  $\Gamma$  by a surface group K.

A Fuchsian group is a discrete subgroup of PSL(2,R). The group PSL(2,R) may be regarded as the group of isometries of the hyperbolic plane or the conformal transformations of the unit disk.

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group  $\Gamma$  by a surface group K.

A Fuchsian group is a discrete subgroup of PSL(2,R). The group PSL(2,R) may be regarded as the group of isometries of the hyperbolic plane or the conformal transformations of the unit disk.

A surface group is a Fuchsian group with no elements of finite order.

< ロト < 同ト < 三ト < 三

Each choice of Fuchsian group  $\Gamma$  and homomorphism onto *G*, represents *G* as a group of isometries (automorphisms) of a Riemann surface.

Each choice of Fuchsian group  $\Gamma$  and homomorphism onto *G*, represents *G* as a group of isometries (automorphisms) of a Riemann surface.

Each such surface has a genus associated with it. The Fuchsian group has a "signature" associated with it and there is a formula which gives the genus of the Riemann surface for each signature.

Each choice of Fuchsian group  $\Gamma$  and homomorphism onto *G*, represents *G* as a group of isometries (automorphisms) of a Riemann surface.

Each such surface has a genus associated with it. The Fuchsian group has a "signature" associated with it and there is a formula which gives the genus of the Riemann surface for each signature.

Finally, the strong symmetric genus of the group G is the smallest genus from among the Riemann surfaces that G acts on preserving orientation.

It is relatively easy to find a homomorphism from a Fuchsian group onto a finite group G. This surjection induces an action of G on a Riemann surface defined by taking a quotient of the upper half - plane (as a model of hyperbolic space) and using G to identify regions.

It is relatively easy to find a homomorphism from a Fuchsian group onto a finite group *G*. This surjection induces an action of *G* on a Riemann surface defined by taking a quotient of the upper half - plane (as a model of hyperbolic space) and using *G* to identify regions.

The genus depends on the non-Euclidean area of the fundamental region. The smaller the area, the smaller the genus.

The hard part is to show that there is no homomorphism from a Fuchsian group whose fundamental region has smaller area onto *G*. Once you have the smallest possible area, you have the Strong Symmetric Genus.

The hard part is to show that there is no homomorphism from a Fuchsian group whose fundamental region has smaller area onto *G*. Once you have the smallest possible area, you have the Strong Symmetric Genus.

So to find  $\sigma^0(G)$  for a finite group *G*, you must find a Fuchsian group and a homomorphism onto *G* with kernel a surface group and the Fuchsian group must have the smallest possible non-Euclidean area for a Fundamental region.

< ロト < 同ト < 三ト < 三

In order to determine the symmetric genus of a finite group G, you need to represent G as the quotient of a Non-Euclidean Crystallographic Group (NEC group)  $\Gamma$  by a surface group K.

In order to determine the symmetric genus of a finite group G, you need to represent G as the quotient of a Non-Euclidean Crystallographic Group (NEC group)  $\Gamma$  by a surface group K.

An NEC group is similar to a Fuchsian group, but has orientation reversing elements as well.

In order to determine the symmetric genus of a finite group G, you need to represent G as the quotient of a Non-Euclidean Crystallographic Group (NEC group)  $\Gamma$  by a surface group K.

An NEC group is similar to a Fuchsian group, but has orientation reversing elements as well.

Finally, the symmetric genus of the group *G* is the smallest genus from among the Riemann surfaces that *G* acts on possibly reversing the orientation of the surface.

#### **Small Numbers**

**Ph.D. Thesis, Stephen Lo, 2018** If *g* is a non-negative integer less than 1000, then  $g = \sigma(G)$  for some finite group *G*, unless |G| = 392, 536, 800, 836, 980.

# **Small Numbers**

**Ph.D. Thesis, Stephen Lo, 2018** If *g* is a non-negative integer less than 1000, then  $g = \sigma(G)$  for some finite group *G*, unless |G| = 392, 536, 800, 836, 980.

Most researchers in this area believe and conjecture that there are no gaps in the symmetric genus spectrum.

# **Small Numbers**

**Ph.D. Thesis, Stephen Lo, 2018** If *g* is a non-negative integer less than 1000, then  $g = \sigma(G)$  for some finite group *G*, unless |G| = 392, 536, 800, 836, 980.

Most researchers in this area believe and conjecture that there are no gaps in the symmetric genus spectrum.

It is also possible to look at the (strong) symmetric genus spectrum for classes of finite groups.

# **Upper and Lower Density**

Let *A* be a set of positive integers. For an integer X, let [1, X] be the set of integers between 1 and X and define  $A(X) = |A \cap [1, X]|$ .

# **Upper and Lower Density**

Let *A* be a set of positive integers. For an integer X, let [1, X] be the set of integers between 1 and X and define  $A(X) = |A \cap [1, X]|$ .

If *A* is a set of integers, its *lower* and *upper asymptotic densities*, denoted  $\underline{\delta}(A)$  and  $\overline{\delta}(A)$ , are given by

$$\underline{\delta}(A) = \liminf_{X \to \infty} \frac{A(X)}{X}$$

and

$$\overline{\delta}(A) = \limsup_{X \to \infty} \frac{A(X)}{X}.$$

# **Density in the Integers**

A set *A* is said to have an *asymptotic density*, if  $\underline{\delta}(A) = \overline{\delta}(A)$ ; when *A* does have an asymptotic density, it is denoted  $\delta(A)$ .

# Density in the Integers

A set *A* is said to have an *asymptotic density*, if  $\underline{\delta}(A) = \overline{\delta}(A)$ ; when *A* does have an asymptotic density, it is denoted  $\delta(A)$ .

Now let *S* be the set of all positive integers that are the strong symmetric genus of some finite group *G*. It follows that  $\delta(S) = 1$ .

# Density in the Integers

A set *A* is said to have an *asymptotic density*, if  $\underline{\delta}(A) = \overline{\delta}(A)$ ; when *A* does have an asymptotic density, it is denoted  $\delta(A)$ .

Now let *S* be the set of all positive integers that are the strong symmetric genus of some finite group *G*. It follows that  $\delta(S) = 1$ .

Clearly the 2003 result of May and Zimmerman is considerably stronger than the above density statement.

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

Dr. May and I ran a summer research experience for 3 undergraduate students. The result was as follows.

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

Dr. May and I ran a summer research experience for 3 undergraduate students. The result was as follows.

**Borror, Morris, Tarr, 2014.** If *J* is the strong symmetric genus of all abelian groups, then  $\delta(J) \ge \frac{643}{2025} > .3175$ .

They did such a nice job that I had to wonder how much further we could go.

The question of whether the asymptotic density for all abelian groups exists had never been answered.

The question of whether the asymptotic density for all abelian groups exists had never been answered.

We showed that  $\delta(J)$  exists and that it is approximately .3284.

The question of whether the asymptotic density for all abelian groups exists had never been answered.

We showed that  $\delta(J)$  exists and that it is approximately .3284.

We also gave necessary and sufficient conditions for a positive integer *g* to be the strong symmetric genus of an abelian group.

#### Formulas III

The following theorems are from Kumchev, A. V., May, C. L., Zimmerman, J. J. (2017). The strong symmetric genus spectrum of abelian groups. Archiv der Mathematik, 108(4), 341-350.

#### Formulas III

The following theorems are from Kumchev, A. V., May, C. L., Zimmerman, J. J. (2017). The strong symmetric genus spectrum of abelian groups. Archiv der Mathematik, 108(4), 341-350.

#### Proposition

The spectrum of abelian groups of rank 3 consists of the congruence class  $g \equiv 1 \pmod{4}$  and the integers g satisfying conditions (iii) or (iv) of the Theorem below.

# Main Theorem

#### Main Theorem

Let  $g \ge 2$ . Then g is the strong symmetric genus of an abelian group if and only if g satisfies one of the following conditions:

- (i)  $g \equiv 1 \pmod{4}$  or  $g \equiv 55 \pmod{81}$ ;
- (ii) g-1 is divisible by  $p^4$  for some odd prime p;
- (iii) g-1 is divisible by  $a^2$  for some odd integer a with  $(a-1) \mid g$ ;
- (iv) g-1 is divisible by  $b^2a^2(a-1)$  for some odd integers a, b > 1, with  $a \equiv 3 \pmod{4}$ .

# **Rank Four Abelian Groups**

#### Proposition

The spectrum of abelian groups of rank 4 is a subset of the integers satisfying conditions (i) or (ii) of the Main Theorem. Moreover, the spectrum of abelian groups of ranks 3 or 4 contains all the integers satisfying condition (ii) of the Main Theorem.

# **Rank Four Abelian Groups**

#### Proposition

The spectrum of abelian groups of rank 4 is a subset of the integers satisfying conditions (i) or (ii) of the Main Theorem. Moreover, the spectrum of abelian groups of ranks 3 or 4 contains all the integers satisfying condition (ii) of the Main Theorem.

Abelian groups of rank 5 or greater have the same genus as an abelian group of rank 3 or 4.

A well-known classical result of **Hurwitz (1893)** states that if a finite group *G* acts **preserving orientation** on a surface of genus *g* where g > 2, then  $|G| \le 84(g-1)$ .

A well-known classical result of **Hurwitz (1893)** states that if a finite group *G* acts **preserving orientation** on a surface of genus *g* where g > 2, then  $|G| \le 84(g-1)$ .

If |G| = 84(g-1), then *G* is called a Hurwitz group.

A well-known classical result of **Hurwitz (1893)** states that if a finite group *G* acts **preserving orientation** on a surface of genus *g* where g > 2, then  $|G| \le 84(g-1)$ .

If |G| = 84(g-1), then *G* is called a Hurwitz group.

If we allow orientation reversing actions, then  $|G| \le 168(g-1)$  and *G* is called an extended Hurwitz group.

If |G| = 84(g-1), then *G* is called a Hurwitz group.

If we allow orientation reversing actions, then  $|G| \le 168(g-1)$  and *G* is called an extended Hurwitz group.

Hurwitz groups and extended Hurwitz groups only occur for a small number of genera *g*. See **Conder, M.** (2010). An update on Hurwitz groups.

The basic inequalities comparing N(g) and M(g) are  $N(g) \le M(g) \le 2N(g)$ .

There are well-known families of extended Hurwitz groups that provide an infinite number of integers g satisfying M(g) = 2N(g). It is also easy to see that there are solvable groups which provide an infinite number of such examples.
