Using Burnside's methods, I constructed multiple models of group actions on surfaces.

Let $G = \langle x, y | x^6 = 1, x^3 = y^2, y^{-1}xy = x^{-1} \rangle$. This is the Dicyclic Group of order 12.

Using Burnside's methods, I constructed multiple models of group actions on surfaces.

Let $G = \langle x, y | x^6 = 1, x^3 = y^2, y^{-1}xy = x^{-1} \rangle$. This is the Dicyclic Group of order 12.

The Genus Action of G is given by the following image of the Triangle Group $\Gamma(3,4,4)$.

Using Burnside's methods, I constructed multiple models of group actions on surfaces.

Let $G = \langle x, y | x^6 = 1, x^3 = y^2, y^{-1}xy = x^{-1} \rangle$. This is the Dicyclic Group of order 12.

The Genus Action of G is given by the following image of the Triangle Group $\Gamma(3,4,4)$.

$$G = \langle s, t | s^4 = t^4 = (st)^3 = 1, st = (ts)^2 \rangle.$$

Using Burnside's methods, I constructed multiple models of group actions on surfaces.

Let $G = \langle x, y | x^6 = 1, x^3 = y^2, y^{-1}xy = x^{-1} \rangle$. This is the Dicyclic Group of order 12.

The Genus Action of G is given by the following image of the Triangle Group $\Gamma(3,4,4)$.

$$G = \langle s, t | s^4 = t^4 = (st)^3 = 1, st = (ts)^2 \rangle.$$

By looking at the number of vertices, edges and faces of this graph, you can see that the Euler characteristic is -2 and so the genus is 2.

Surface Representation of the Dicyclic Group

Coy L. May and Jay Zimmerman (Towson Unive THE GENUS SPECTRUM OF FINITE ABELIAN G

Surface Representation of a Group of Order 32

Procedure for determining the Genus

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group Γ by a surface group K.

Procedure for determining the Genus

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group Γ by a surface group K.

A Fuchsian group is a discrete subgroup of PSL(2,R). The group PSL(2,R) may be regarded as the group of isometries of the hyperbolic plane or the conformal transformations of the unit disk.

Procedure for determining the Genus

In order to determine the strong symmetric genus of a finite group G, you need to represent G as the quotient of a Fuchsian group Γ by a surface group K.

A Fuchsian group is a discrete subgroup of PSL(2,R). The group PSL(2,R) may be regarded as the group of isometries of the hyperbolic plane or the conformal transformations of the unit disk.

A surface group is a Fuchsian group with no elements of finite order.

Procedure for determining the Genus II

Each choice of Fuchsian group Γ and mapping onto *G*, represents *G* as a group of automorphisms of a Riemann surface.

Procedure for determining the Genus II

Each choice of Fuchsian group Γ and mapping onto *G*, represents *G* as a group of automorphisms of a Riemann surface.

Each such surface has a genus associated with it. The Fuchsian group has a "signature" associated with it and there is a formula which gives the genus of the Riemann surface for each signature.

Procedure for determining the Genus II

Each choice of Fuchsian group Γ and mapping onto *G*, represents *G* as a group of automorphisms of a Riemann surface.

Each such surface has a genus associated with it. The Fuchsian group has a "signature" associated with it and there is a formula which gives the genus of the Riemann surface for each signature.

Finally, the strong symmetric genus of the group *G* is the smallest genus from among the Riemann surfaces that *G* acts on preserving orientation.

Natural Questions

It is natural to try to compute the groups whose genus is a small positive integer.

Natural Questions

It is natural to try to compute the groups whose genus is a small positive integer.

A well-known classical result of Hurwitz (1893) states that $|G| \le 84(g-1)$ for genus *g*, where g > 2.

Natural Questions

It is natural to try to compute the groups whose genus is a small positive integer.

A well-known classical result of Hurwitz (1893) states that $|G| \le 84(g-1)$ for genus *g*, where g > 2.

Therefore, there are only a finite number of groups whose genus is a positive integer greater than 2. It is natural to try to compute the groups whose genus is a small positive integer.

A well-known classical result of Hurwitz (1893) states that $|G| \le 84(g-1)$ for genus *g*, where g > 2.

Therefore, there are only a finite number of groups whose genus is a positive integer greater than 2. It is also natural to look at certain classes of groups with similar presentations and find a formula which gives the genus of each group in the class.

Natural Questions II

Another natural problem is to determine the positive integers that occur as the strong symmetric genus of a group (or a particular type of group).

Natural Questions II

Another natural problem is to determine the positive integers that occur as the strong symmetric genus of a group (or a particular type of group).

May & Zimmerman, 2003. There is a group of strong symmetric genus *n* for each value of the integer *n*.

Another natural problem is to determine the positive integers that occur as the strong symmetric genus of a group (or a particular type of group).

May & Zimmerman, 2003. There is a group of strong symmetric genus *n* for each value of the integer *n*.

The set of positive integers that is the strong symmetric genus of some group is called the strong symmetric genus spectrum.

Upper and Lower Density

Let *A* be a set of positive integers. For an integer X, let [1, X] be the set of integers between 1 and X and define $A(X) = |A \cap [1, X]|$.

Upper and Lower Density

Let *A* be a set of positive integers. For an integer X, let [1, X] be the set of integers between 1 and X and define $A(X) = |A \cap [1, X]|$.

If *A* is a set of integers, its *lower* and *upper asymptotic densities*, denoted $\underline{\delta}(A)$ and $\overline{\delta}(A)$, are given by

$$\underline{\delta}(A) = \liminf_{X \to \infty} \frac{A(X)}{X}$$

and

$$\overline{\delta}(A) = \limsup_{X \to \infty} \frac{A(X)}{X}.$$

Density in the Integers

A set *A* is said to have an *asymptotic density*, if $\underline{\delta}(A) = \overline{\delta}(A)$; when *A* does have an asymptotic density, it is denoted $\delta(A)$.

Density in the Integers

A set *A* is said to have an *asymptotic density*, if $\underline{\delta}(A) = \overline{\delta}(A)$; when *A* does have an asymptotic density, it is denoted $\delta(A)$.

Now let *S* be the set of all positive integers that are the strong symmetric genus of some finite group *G*. It follows that $\delta(S) = 1$.
Density in the Integers

A set *A* is said to have an *asymptotic density*, if $\underline{\delta}(A) = \overline{\delta}(A)$; when *A* does have an asymptotic density, it is denoted $\delta(A)$.

Now let *S* be the set of all positive integers that are the strong symmetric genus of some finite group *G*. It follows that $\delta(S) = 1$.

Clearly the 2003 result of May and Zimmerman is considerably stronger than the above density statement.

Density of the Abelian Spectrum

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

Density of the Abelian Spectrum

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

We will show that $\delta(A)$ exists and that it is approximately .3284.

Density of the Abelian Spectrum

Next let *A* be the set of all positive integers that are the strong symmetric genus of some finite abelian group *G*.

We will show that $\delta(A)$ exists and that it is approximately .3284.

We will also give necessary and sufficient conditions for a positive integer *g* to be the strong symmetric genus of an abelian group.

Formulas I

Recall that every finite abelian group *G* has a canonical representation $G \cong Z_{m_1} \times Z_{m_2} \times \cdots \times Z_{m_r}$, with standard invariants m_1, m_2, \ldots, m_r subject to $m_1 > 1$ and $m_i | m_{i+1}$ for $1 \le i < r$.

Formulas I

Recall that every finite abelian group *G* has a canonical representation $G \cong Z_{m_1} \times Z_{m_2} \times \cdots \times Z_{m_r}$, with standard invariants m_1, m_2, \ldots, m_r subject to $m_1 > 1$ and $m_i | m_{i+1}$ for $1 \le i < r$.

Maclachlan (1965) proved that if *G* is an abelian group of rank $r \ge 3$, with $|G| \ge 10$, then

$$\sigma^{0}(G) = 1 + \frac{|G|}{2} \min_{0 \le \gamma \le r/2} \left\{ 2\gamma - 2 + \sum_{i=1}^{r-2\gamma} \left(1 - \frac{1}{m_{i}} \right) + \left(1 - \frac{1}{m_{r-2\gamma}} \right) \right\}.$$
(1)

ロトス得トスラトスラト・ラ

Formulas II

For example, when a > 1 and $a^3n \ge 10$, Maclachlan's formula yields

$$\sigma^0(\mathbb{Z}_a \times \mathbb{Z}_a \times \mathbb{Z}_{an}) = 1 - a^2 + a^2(a-1)n.$$

Formulas II

For example, when a > 1 and $a^3 n \ge 10$, Maclachlan's formula yields

$$\sigma^0(\mathbb{Z}_a \times \mathbb{Z}_a \times \mathbb{Z}_{an}) = 1 - a^2 + a^2(a-1)n.$$

In particular, when a = 2, this reveals that *S* contains the entire residue class $g \equiv 1 \pmod{4}$.

Formulas II

For example, when a > 1 and $a^3 n \ge 10$, Maclachlan's formula yields

$$\sigma^0(\mathbb{Z}_a \times \mathbb{Z}_a \times \mathbb{Z}_{an}) = 1 - a^2 + a^2(a-1)n.$$

In particular, when a = 2, this reveals that *S* contains the entire residue class $g \equiv 1 \pmod{4}$.

Also when *a* is odd, $g \equiv 1 - a^2 \pmod{a^2(a-1)}$ and this is equivalent to g-1 is divisible by a^2 for some odd integer *a* with (a-1)|g by the Chinese Remainder Theorem.

Formulas III

When $b \ge 2$ and bn > 2, Maclachlan's formula gives

$$\sigma^{0}(Z_{a} \times Z_{ab} \times Z_{abn}) = 1 + b^{2}a^{2}(a-1)n.$$
(2)

In all cases, except when *a* and *b* are odd, with $a \equiv 3 \pmod{4}$, $g \equiv 1 \pmod{4}$.

Formulas III

When $b \ge 2$ and bn > 2, Maclachlan's formula gives

$$\sigma^{0}(Z_{a} \times Z_{ab} \times Z_{abn}) = 1 + b^{2}a^{2}(a-1)n.$$
(2)

In all cases, except when *a* and *b* are odd, with $a \equiv 3 \pmod{4}$, $g \equiv 1 \pmod{4}$.

Proposition

The spectrum of abelian groups of rank 3 consists of the congruence class $g \equiv 1 \pmod{4}$ and the integers g satisfying conditions (iii) or (iv) of the Theorem below.

Main Theorem

Main Theorem

Let $g \ge 2$. Then $g \in S$ if and only if g satisfies one of the following conditions:

- (i) $g \equiv 1 \pmod{4}$ or $g \equiv 55 \pmod{81}$;
- (ii) g-1 is divisible by p^4 for some odd prime p;
- (iii) g-1 is divisible by a^2 for some odd integer a with $(a-1) \mid g$;
- (iv) g-1 is divisible by $b^2a^2(a-1)$ for some odd integers a, b > 1, with $a \equiv 3 \pmod{4}$.

Rank Four Abelian Groups

Proposition

The spectrum of abelian groups of rank 4 is a subset of the integers satisfying conditions (i) or (ii) of the Main Theorem. Moreover, the spectrum of abelian groups of ranks 3 or 4 contains all the integers satisfying condition (ii) of the Main Theorem.

Rank Four Abelian Groups

Proposition

The spectrum of abelian groups of rank 4 is a subset of the integers satisfying conditions (i) or (ii) of the Main Theorem. Moreover, the spectrum of abelian groups of ranks 3 or 4 contains all the integers satisfying condition (ii) of the Main Theorem.

Proof: Notice that for an abelian group to have rank 4, it must have a subgroup isomorphic to Z_p^4 for some prime *p*.

If p = 2, then $g \equiv 1 \pmod{4}$. So we may assume that the abelian group has a subgroup isomorphic to Z_a^4 for some odd integer *a*.

If p = 2, then $g \equiv 1 \pmod{4}$. So we may assume that the abelian group has a subgroup isomorphic to Z_a^4 for some odd integer *a*.

When $a \ge 5$, then $\sigma^0(A) = 1 + |A|$ for the rank 4 abelian group *A*. For a = 3, then $\sigma^0(A) = 1 + |A|$ or $\sigma^0(A) \equiv 1$ (mod 4) for all except a few cases.

If p = 2, then $g \equiv 1 \pmod{4}$. So we may assume that the abelian group has a subgroup isomorphic to Z_a^4 for some odd integer *a*.

When $a \ge 5$, then $\sigma^0(A) = 1 + |A|$ for the rank 4 abelian group *A*. For a = 3, then $\sigma^0(A) = 1 + |A|$ or $\sigma^0(A) \equiv 1$ (mod 4) for all except a few cases.

For the exceptional cases with a = 3, $\sigma^0(A) \equiv 55 \pmod{81}$.

If p = 2, then $g \equiv 1 \pmod{4}$. So we may assume that the abelian group has a subgroup isomorphic to Z_a^4 for some odd integer *a*.

When $a \ge 5$, then $\sigma^0(A) = 1 + |A|$ for the rank 4 abelian group *A*. For a = 3, then $\sigma^0(A) = 1 + |A|$ or $\sigma^0(A) \equiv 1$ (mod 4) for all except a few cases.

For the exceptional cases with a = 3, $\sigma^{0}(A) \equiv 55 \pmod{81}$.

Conversely, all numbers *g* of the form $1 + p^4 n$ are the genus of groups of rank 3 or 4.

(日)

High Rank Abelian Groups

Let *A* be an abelian group of rank $n \ge 5$. So *A* has a subgroup isomorphic to Z_a^n . If *a* is even, then $\sigma^0(A) \equiv 1 \pmod{4}$ and $\sigma^0(A) = \sigma^0(Z_2 \times Z_2 \times Z_{2n})$ for some *n*.

High Rank Abelian Groups

Let *A* be an abelian group of rank $n \ge 5$. So *A* has a subgroup isomorphic to Z_a^n . If *a* is even, then $\sigma^0(A) \equiv 1 \pmod{4}$ and $\sigma^0(A) = \sigma^0(Z_2 \times Z_2 \times Z_{2n})$ for some *n*.

If *a* is odd, then there is a rank four group *B* satisfying |A| = |B| and so $\sigma^0(A) = \sigma^0(B)$.

High Rank Abelian Groups

Let *A* be an abelian group of rank $n \ge 5$. So *A* has a subgroup isomorphic to Z_a^n . If *a* is even, then $\sigma^0(A) \equiv 1 \pmod{4}$ and $\sigma^0(A) = \sigma^0(Z_2 \times Z_2 \times Z_{2n})$ for some *n*.

If *a* is odd, then there is a rank four group *B* satisfying |A| = |B| and so $\sigma^0(A) = \sigma^0(B)$.

Therefore, the genus spectrum is given by looking at the strong symmetric genus of groups of rank 3 or rank 4.

Let S_j denote those $g \in S$ that satisfy the *j*th condition of the theorem but none of the earlier conditions.

Let S_j denote those $g \in S$ that satisfy the *j*th condition of the theorem but none of the earlier conditions.

For example, by the inclusion-exclusion principle, the density of S_1 (i.e., the union of the congruence classes $g \equiv 1 \pmod{4}$ and $g \equiv 55 \pmod{81}$ is

Let S_j denote those $g \in S$ that satisfy the *j*th condition of the theorem but none of the earlier conditions.

For example, by the inclusion-exclusion principle, the density of S_1 (i.e., the union of the congruence classes $g \equiv 1 \pmod{4}$ and $g \equiv 55 \pmod{81}$ is

$$\delta_1 = \frac{1}{4} + \frac{1}{81} - \frac{1}{324} = \frac{7}{27}.$$

Let $\alpha_4(n)$ denote the characteristic function of the integers *n* such that $p^4 \nmid n$ for any prime *p*.

Let $\alpha_4(n)$ denote the characteristic function of the integers *n* such that $p^4 \nmid n$ for any prime *p*.

It is known that if gcd(a, q) = 1, then

$$\sum_{\substack{n \le X \\ n \equiv a \pmod{q}}} \alpha_4(n) = C_q X + O(X^{1/3}).$$

We use this to show that the number T(X) of integers $g \in S_2$ with $g \equiv 2 \pmod{4}$ and $g \leq X$ is

$$T(X) = \frac{X}{4} - \sum_{\substack{h \le X \\ h \equiv 1 \pmod{4}}} \alpha_4(n) = \frac{X}{4} \left(1 - \frac{16}{15\zeta(4)} \right) + O(X^{1/3}).$$

(口) (同) (三) (三

We use this to show that the number T(X) of integers $g \in S_2$ with $g \equiv 2 \pmod{4}$ and $g \leq X$ is

$$T(X) = \frac{X}{4} - \sum_{\substack{h \le X \\ h \equiv 1 \pmod{4}}} \alpha_4(n) = \frac{X}{4} \left(1 - \frac{16}{15\zeta(4)} \right) + O(X^{1/3}).$$

and so the density of S_2 is

$$\delta_2 = \frac{20}{27} - \frac{79}{100\zeta(4)} \approx 0.0108.$$

(*)

for some odd a > 1.

The number of such g that fail condition (ii) is

$$\begin{split} S_{3}'(X) &= \sum_{\substack{g \in \mathcal{A} \\ g \leq X}} \alpha_{4}(g-1) + O(1) \\ &= \sum_{d \leq D} \mu(d) \sum_{3 \leq a \leq D^{2}} \sum_{\substack{g \in \mathcal{A}(d,a) \\ g \leq X}} 1 + O(XD^{-3}), \end{split}$$

where $D = \lfloor \sqrt{\ln X} \rfloor$, $\mathcal{A}(d, a)$ is the set of $g \in \mathcal{A}$ such that $d^4 \mid (g-1)$ and *a* is the least odd for which (*) holds.

Using inclusion-exclusion, it is possible to estimate the density of $\mathcal{A}(d, a)$ and to prove that, as $X \to \infty$,

$$S'_{3}(X) = X \sum_{d \le D} \mu(d) \sum_{3 \le a \le D^{2}} \delta(d, a) + o(X),$$

where $\delta(d, a)$ is a certain arithmetic function.

Using inclusion-exclusion, it is possible to estimate the density of $\mathcal{A}(d, a)$ and to prove that, as $X \to \infty$,

$$S'_{3}(X) = X \sum_{d \le D} \mu(d) \sum_{3 \le a \le D^{2}} \delta(d, a) + o(X),$$

where $\delta(d, a)$ is a certain arithmetic function.

From this and another similar calculation, we deduce that

 $\delta_3 \approx 0.0564.$

The calculation of the density of S_4 is similar to that of the density of S_3 and yields a value

 $\delta_4 \approx 0.0019.$

The calculation of the density of S_4 is similar to that of the density of S_3 and yields a value

 $\delta_4 \approx 0.0019.$

Altogether, we have

 $\delta(\mathbb{S}) = \delta_1 + \dots + \delta_4 \approx 0.3284.$

The Real Genus

Every finite abelian group *G* has a representation $G \cong Z_{e_1} \times \cdots \times Z_{e_m} \times Z_{d_1} \times \cdots \times Z_{d_\ell} \times Z_2^n$, where e_i is a multiple of 4 $d_j \ge 3$ is odd and as we move from left to right all invariants divide the previous one.

The Real Genus

Every finite abelian group *G* has a representation $G \cong Z_{e_1} \times \cdots \times Z_{e_m} \times Z_{d_1} \times \cdots \times Z_{d_\ell} \times Z_2^n$, where e_i is a multiple of 4 $d_j \ge 3$ is odd and as we move from left to right all invariants divide the previous one.

McCullough (1990) obtained the formulas for the real genus of abelian non-cyclic groups by using graph theoretic techniques. One of 4 such formulas is given below.

$$\rho(G) = 1 + |G| \left(n - 1 + \sum_{i=1}^{\ell} \left(1 - \frac{1}{d_i} \right) + \sum_{j=n+1}^{m} \left(1 - \frac{1}{e_j} \right) \right).$$

The difference in the formulas

McCullough's four formulas really just specify where the minimum occurs in a formula similar to Maclachlan's formula.

The difference in the formulas

McCullough's four formulas really just specify where the minimum occurs in a formula similar to Maclachlan's formula.

In Maclachlan's formula the last term is repeated. This is not true in any of McCullough's formulas. This small change makes a huge difference. It changes where the minimum value for the summation occurs.

The difference in the formulas

McCullough's four formulas really just specify where the minimum occurs in a formula similar to Maclachlan's formula.

In Maclachlan's formula the last term is repeated. This is not true in any of McCullough's formulas. This small change makes a huge difference. It changes where the minimum value for the summation occurs.

For example, this small change means that we must consider abelian groups of all ranks when looking at the real genus spectrum.

It is easy to show that

$\rho(Z_2 \times Z_2 \times Z_{2c}) = 1 + 4c.$

Theorem If *A* is an abelian group of odd order, then $\rho(A) \equiv 0 \pmod{4}$.

Theorem

Let A be a finite abelian group of even order with $\rho(A)$ positive. If $\rho(A)$ is not congruent to 1 (mod 4), then the Sylow 2-subgroup of A is cyclic.

Now by looking at cases, we get the following result.

A = A = A = A = A

Now by looking at cases, we get the following result.

Theorem If *A* is a finite abelian group, then $\rho(A)$ is not congruent to 3 (mod 4). Now by looking at cases, we get the following result.

Theorem If *A* is a finite abelian group, then $\rho(A)$ is not congruent to 3 (mod 4).

As in the strong symmetric genus case, if the rank of the abelian group is at least 3, then g-1 contains the square of an odd prime.

Now by looking at cases, we get the following result.

Theorem If *A* is a finite abelian group, then $\rho(A)$ is not congruent to 3 (mod 4).

As in the strong symmetric genus case, if the rank of the abelian group is at least 3, then g-1 contains the square of an odd prime.

Theorem

Let $g \ge 4$. If $g \in S$ and g - 1 is squarefree, then $g = \rho(A)$ for an abelian group A of rank two.

We also obtain the following necessary condition for an integer *g* to be in the spectrum.

Theorem

Let $g \ge 4$. If $g \in S$, then g satisfies one of the following conditions:

- (i) $g \equiv 1 \pmod{4}$;
- (ii) $g \equiv 4 \pmod{6}$ or $g \equiv 16 \pmod{20}$;
- (iii) g-1 is divisible by a for some odd integer a such that (a-1) divides g;
- (iv) g-1 is divisible by p^2 for some odd prime p;

Density

It is a classical result that the squarefree integers have asymptotic density $6/\pi^2 \approx .6079$. The squarefree integers are distributed among the three classes of integers congruent to 1,2,3 (mod 4). Further, Jameson proved that the asymptotic density of the odd squarefree integers is $4/\pi^2 \approx .4053$. Using these results, we have the following bounds for the density.
